Chapter 1

Functions

1.1 poly.groebner – Gröbner Basis

The groebner module is for computing Gröbner bases for multivariate polynomial ideals.

This module uses the following types:

polynomial :

polynomial is the polynomial generated by function **polynomial**.

order :

order is the order on terms of polynomials.

1.1.1 buchberger – naïve algorithm for obtaining Gröbner basis

buchberger(generating: *list*, order: *order*) → [*polynomials*]

Return a Gröbner basis of the ideal generated by given generating set of polynomials with respect to the order.

Be careful, this implementation is very naive.

The argument generating is a list of **Polynomial**; the argument order is an order.

1.1.2 normal_strategy – normal algorithm for obtaining Gröbner basis

normal_strategy(generating: *list*, order: *order*) → [*polynomials*]

Return a Gröbner basis of the ideal generated by given generating set of polynomials with respect to the order.

This function uses the ‘normal strategy’.

The argument `generating` is a list of **Polynomial**; the argument `order` is an order.

1.1.3 `reduce_groebner` – reduce Gröbner basis

```
reduce_groebner(gbasis: list, order: order) → [polynomials]
```

Return the reduced Gröbner basis constructed from a Gröbner basis.

The output satisfies that:

- $\text{lb}(f)$ divides $\text{lb}(g) \Rightarrow g$ is not in reduced Gröbner basis, and
- monic.

The argument `gbasis` is a list of polynomials, a Gröbner basis (not merely a generating set).

1.1.4 `s_polynomial` – S-polynomial

```
s_polynomial(f: polynomial, g: polynomial, order: order)
→ [polynomials]
```

Return S-polynomial of `f` and `g` with respect to the order.

$$S(f, g) = (\text{lc}(g) * T / \text{lb}(f)) * f - (\text{lc}(f) * T / \text{lb}(g)) * g,$$

where $T = \text{lcm}(\text{lb}(f), \text{lb}(g))$.

Examples

```
>>> f = multiutil.polynomial({(1,0):2, (1,1):1},rational.theRationalField, 2)
>>> g = multiutil.polynomial({(0,1):-2, (1,1):1},rational.theRationalField, 2)
>>> lex = termorder.lexicographic_order
>>> groebner.s_polynomial(f, g, lex)
UniqueFactorizationDomainPolynomial({(1, 0): 2, (0, 1): 2})
>>> gb = groebner.normal_strategy([f, g], lex)
>>> for gb_poly in gb:
...     print gb_poly
```

```

...
UniqueFactorizationDomainPolynomial({(1, 1): 1, (1, 0): 2})
UniqueFactorizationDomainPolynomial({(1, 1): 1, (0, 1): -2})
UniqueFactorizationDomainPolynomial({(1, 0): 2, (0, 1): 2})
UniqueFactorizationDomainPolynomial({(0, 2): -2, (0, 1): -4.0})
>>> gb_red = groebner.reduce_groebner(gb, lex)
>>> for gb_poly in gb_red:
...     print gb_poly
...
UniqueFactorizationDomainPolynomial({(1, 0): Rational(1, 1), (0, 1): Rational(1, 1)})
UniqueFactorizationDomainPolynomial({(0, 2): Rational(1, 1), (0, 1): 2.0})

```
